# Design a Low Cost 1000 Watt Power Amplifier for Rural Nigeria 

Arobieke O. Oluwole<br>Electrical Engineering Department, Rufus Giwa Polytechnic, Owo.<br>Email:- oluarobieke@yahoo.com

#### Abstract

The need to get cheap and workable equipment to the rural areas cannot be overemphasised. The rural area of Nigeria represents more than half of the population. As enlightments grows, so also is the demand for "the good things of life". The opportunity to use a rugged and durable, high quality amplifier is the brainwork behind this paper.

Keywords-OP-Amp, resistor, capacitor, power, Nigeria

## INTRODUCTION

### 1.0DESIGN OF 1000 WATT POWER AMPLIFIER

It is known from the intention that this paper is foe 1000 watts. So the output power is 1000 watts. This will be supplied from a rectified power supply of 12 V with a projected load of $8 \Omega$

The various stages to be equally designed are the power supply, amplifying and the output units.

## POWER SUPPLY UNIT

This stage is very important because it involves the conversion of the alternating current (A.C.) to direct current (D.C.) form required by the various stages within the system. It consists of a transformer, rectifier and a filter. It has a step down transformer with 45 volts output voltage.

## TRANSFORMER CIRCUIT

For the transformer (fig 1) let us assume that the primary winding consist of 500 turns with an input voltage of 220 V . The output voltage is 45 V . The desired turns at the secondary winding will be determined by the transformed ratio.

Fig. 1: Transformer
$\frac{V_{S}}{V_{P}}=\frac{N_{S}}{N_{P}}$
Where
$\mathrm{V}_{\mathrm{S}}=$ Secondary Voltage
$V_{P}=$ Primary Voltage
$N_{S}=$ Secondary Turns
$N_{P}=$ Primary Turns

$$
\frac{45}{220}=\frac{N_{S}}{500} \Rightarrow \frac{500 \times 45}{220}=N_{S}=102 \text { Turns }
$$

So the secondary winding consists of 102turns.

## RECTIFYING CIRCUIT

The rectifying diode voltage (peak) $=50 \mathrm{~V}$
Power $(P)=1000 w$
Voltage (V) $=50 \mathrm{~V}$
$\mathrm{P}=\mathrm{VI}$
Where I is the current

$$
\therefore I_{(\max )}=\frac{P}{V_{(\max )}}=\frac{400}{50}=8 A
$$

Fig. 2: Rectifying Circuit
The diode rating that can accommodate the required current without heating is IN5400

## FILTERING CIRCUIT

The smoothing or filtering circuit, the output of two capacitors will pass through the resistors that are connected in parallel. To calculate the value of the capacitors used in the filtering circuit.

$$
\begin{aligned}
& V_{\text {r.m.s. }}=45 \mathrm{~V} \\
& \mathrm{~V}_{\text {Peak }}=\mathrm{V}_{\max }=\sqrt{2} \times \mathrm{V}_{\text {rms }}=\sqrt{2} \times 45=63.63 \mathrm{~V} \\
& \mathrm{~V}_{\text {d.c }}=0.636 \times 63.63=40.5 \mathrm{~V} \\
& \mathrm{~V}_{\text {ripple }}=63.63-40.5=23.13 \mathrm{~V}
\end{aligned}
$$

$$
V_{\text {ripple }}=63.63-40.5=23.13 \mathrm{~V}
$$

$\mathrm{V}_{\text {ripple }}($ peak to peak $)=2 \times 23.13=46.26 \mathrm{~V}$
The required ripple voltage should be $5 \%$ peak to peak

$$
=\frac{5}{100} \times 46.26=2.31 \mathrm{~V}
$$

Capacitance
$=\frac{T \times V_{\max }}{\text { Projected Load } \times \text { Required Ripple Voltage }}$

Where $T=$ period $=1 / f$ where $F$ is the frequency $=$ 50HZ

$$
\therefore T=\frac{1}{50}=0.02 \operatorname{Sec}
$$

Projected load $=8 \Omega$
Assuring that $R_{1}=R_{2}=1 \mathrm{k} \Omega$
Capacitance $=\frac{0.02 \times 63.63}{2.31 \times 8}=\frac{1.2726}{18.48}$
$=6886 \times 10^{-6} F=6886 \mu F$
And $\mathrm{C}_{1}=\mathrm{C}_{2}=6886 \mu \mathrm{~F}$
The reactive value is $6800 \mu \mathrm{~F}$ which is capable of performing the function of the calculated value.

Fig. 3: Filtering Circuit
The secondary voltage is 45 V for one side of the winding. Therefore, the capacitor rating voltage will be $45 \times 2=90 \mathrm{~V}$. So, a capacitor $6800 \mu \mathrm{~F} 80 \mathrm{~V}$ rating will be preferred for efficient filtering and operation. The resistors $R_{1}$ and $R_{2}$ of Fig. 3 are assumed to be $1 \mathrm{k} \Omega$

Fig. 4: Complete Power Supply Stage

## AMPLIFIER STAGE

It makes use of an OP- Amp (JRC 4558). It is used due to its high gain and minimum distortion in the audio frequency range. For efficiency in the system, the gain should be between 10 dB and 20 dB

Assume voltage gain $=20 \mathrm{~dB}$
For effectiveness the values of resistor lies between $10 \mathrm{k} \Omega$ and $200 \mathrm{k} \Omega$.

Fig. 5: Amplifier Circuit
Assuming that $\mathrm{R}_{4}$ from fig. 5 above $=56 \mathrm{k} \Omega$

$$
\begin{aligned}
& \text { And } C=\frac{1}{2 \pi f X_{C}} \text { where } f=50 \mathrm{~Hz}_{\mathrm{z}} \\
& C=\frac{1}{2 \times 3.142 \times 56 \times 10^{3} \times 50}=\frac{10^{-5}}{56}=0.1 \mu \mathrm{~F}
\end{aligned}
$$

To calculate the value of the feedback resistor $\left(\mathrm{R}_{\mathrm{f}}\right)$, we have

$$
\text { Gain }=\frac{R_{F}}{R_{i n}}
$$

$$
20=\frac{R_{F}}{56} \Rightarrow R_{F}=20 \times 56 \times 10^{3}=1120 \mathrm{k} \Omega
$$

The preferred and readily available value is $1200 \mathrm{k} \Omega$. Also, for the variable resistor at the input terminal a $100 \mathrm{k} \Omega$ resistor is used for efficiency.

## OUTPUT STAGE

This stage of the power amplifier makes use of power transistors (MOSFETS). There are eight (8) MOSFETs in all, that is, 4 per channel. There are two P - channel MOSFET (IREP250N) and two N channel MOSFET (IREP9240).

Fig. 6: Power Amplifying Stage
The minimum voltage that must be applied to the output stage for it to give the required output is given by.

$$
V_{D D}=V_{D}+I_{D} R_{L}
$$

Where
$V_{D}=$ Drain Voltage
$I_{D}=$ Drain Current
$R_{L}=$ Load Resistor
Drain Voltage $=40 \mathrm{~V}$ and
power per channel $=200 \mathrm{~W}$
from $P=I V$
$I=\frac{P}{V}=\frac{200}{40}=5 A$
Load Resistor $=8 \Omega$
From $V_{D D}=V_{D}+I_{D} R_{L}$
$V_{D D}=40+(8 \times 5)$
$V_{D D}=40+40=80 \mathrm{~V}$
$V_{P P}$ is the peak to peak voltage swing at the output of the power amplifier
$\therefore P_{r . m . s}=\frac{V_{P P}^{2}}{2^{2} R_{L}}$
$V_{P P}^{2}=\frac{P_{r, m . s} \times 2^{2} R_{L}}{\sqrt{P_{r . m . s} \times 2 R_{L}}}=\sqrt{400 \times 2^{2} \times 8}=\sqrt[2]{8 \times 400}=\sqrt[2]{3200}=113.14 \mathrm{~V}$
And $I_{P P}=$ peak to peak current delivered to the loudspeaker
$I_{P P}=\frac{V_{P P}}{2 R_{L}}=\frac{113.14}{2 \times 8}=\frac{113.14}{16}=7.07 \mathrm{~A}$
Power delivered by each channel is given by
$\mathrm{P}_{2}=\mathrm{P}_{1}=\mathrm{VI}$
Where $\mathrm{V}=40 \mathrm{~V}$ and $\mathrm{I}=5 \mathrm{Amps}$
$P_{1}=P_{2}=40 \times 5=200 \mathrm{~W}$
$\therefore$ Total Power delivered by the two channels is given by
$P_{T}=P_{1}+P_{2}=200+200=400 \mathrm{~W}$.

## CONCLUSION

Looking closely at the attendant cost (Table 1); it can be seen to be about one third of the price of the equivalent 1000 watts amplifier in the open market.
